

Pointing the domain at the new site

A DNS cutover guide for `trustedtermiteandpest.com`, currently served by Landingsite (Ailanding)

Live DNS and registry records read 27 August 2026. Everything in §1 was measured, not assumed. Re-check before you act if this document is more than a few weeks old.

Before anything else — what this guide does and does not know

It knows the domain. Every value in the next section was read live from the public DNS and the registry on the date stamped above. Those are facts you can verify yourself in a minute, and the commands to do it are in §6.

It does not know Landingsite's control panel. We have no login, and they publish no DNS documentation we could find. So this guide will not tell you to "click the blue Settings button" — anybody who gives you exact screenshots of a panel they cannot see is guessing, and a guess in a DNS panel takes a live business offline. Instead, §4 tells you what the controls are called across the industry, and what each one has to end up saying.

The one thing to get right

DNS has three separate jobs that people collapse into one word. **The registrar** is who you rent the name from — here, Name.com. **The DNS host** is whose servers answer questions about the name — here, Landingsite. **The web host** is where the site actually lives — today Landingsite, and the new one is Vercel. Moving the site does not require moving the registrar. It only requires changing what the DNS host says.

1 · What is true right now

RECORD	CURRENT VALUE	MATTERS BECAUSE
Registrar	Name.com, Inc.	Not Landingsite. The registrar account is where nameservers and transfers are controlled.
Registry status	clientTransferProhibited	Transfer lock is ON. It must be lifted before the domain can move registrar.
Registered	29 October 2025	Under 12 months old.
Expires	29 October 2026	About 63 days away. See the warning below.
Nameservers	ns1-ns4.landingsite.ai	Landingsite answers all DNS for this domain. Nothing moves without either their panel or a nameserver change.
Apex A	166.117.246.71 75.2.29.147	Two records. Both must be removed on cutover, not just one.
www CNAME	proxy-ssl.getlandingsite.com	The live site is served through a Landingsite proxy. This is the record that carries your traffic.
TXT	google-site-verification=L4b3yuf1...	Preserve this. Deleting it breaks Google Search Console verification.
MX	None	No email on this domain — see the good news below.
CAA	None	Nothing blocking a new SSL certificate.
AAAA	None	Good — Vercel does not support IPv6 for third-party domains.
_acme-challenge	None	Good — a stale one is a common cause of SSL failing after a move.

TTLs	A / CNAME / TXT: 1 hour NS: 6 hours	How long the old answer stays cached. Determines how fast you can undo a mistake.
------	---	---

2 · Three findings that change the plan

⚠ The domain expires in about 63 days — on 29 October 2026

This is more urgent than the cutover and it is not on anybody's list. If it lapses, the site goes dark and the name enters a redemption process that is expensive and slow to reverse. **Confirm today who is paying the renewal and that auto-renew is on**, at Name.com or through Landingsite. Do this before you touch a single DNS record — there is no point cutting over to a domain that expires eight weeks later.

⚠ The domain is transfer-locked

The registry reports `clientTransferProhibited`. That is normal and it is not sabotage — most registrars set it by default. But it means a registrar transfer needs the lock lifted and an auth code issued, which needs access to the Name.com account. Also note ICANN forces a **60-day wait** between a new registration and a transfer; the domain is past that, so the clock is not a problem here.

✓ There is no email on this domain — the usual disaster cannot happen

The single most common way a DNS cutover ruins someone's week is that the nameservers change, the `MX` records are not carried across, and company email silently stops. **This domain has no MX records at all**, which fits — the business runs on a Gmail address. So email cannot break. That materially lowers the risk of both routes below.

3 · Two routes. Pick one.

Both end with the same site live on the same domain. They differ in what you have to touch and how fast you can undo it.

Route A **RECOMMENDED**

Leave the nameservers alone. Change two records inside Landingsite's DNS panel.

Why: smallest possible change. One hour to undo, because the TTL is one hour. No registrar access needed. The Google verification record stays untouched because you never rebuild the zone.

Cost: Landingsite keeps answering DNS for a domain whose site they no longer host — so you stay dependent on their panel and their goodwill.

Route B **CLEANER, SLOWER**

Change the nameservers at Name.com to point at Vercel.

Why: full independence. Landingsite is out of the path entirely and never has to be asked for anything again.

Cost: 24–48 hours to propagate rather than one hour, and you must re-create every record you want to keep — the Google verification TXT above all — *at Vercel, before you switch*. Needs Name.com access.

Our recommendation

Do Route A now, and Route B later if you want it. Route A gets the new site live with an escape hatch measured in minutes. Route B is a tidy-up that can happen any calm week afterwards. Doing both at once means that if something breaks, you cannot tell which change broke it.

4 · Route A, step by step

⚠ Do not use an IP address you found in a blog post

Vercel's own documentation says the correct A record "is whatever your domain card shows" — `76.76.21.21` is common but newer projects are given different addresses, and the `CNAME` target is unique per project (it looks like `d1d4fc829fe7bc7c.vercel-dns-017.com`). **Read both values off your own Vercel dashboard.** Everything below assumes you have done step 1 first.

- 1 Add the domain in Vercel first, and write down what it tells you.** Project → Settings → Domains → Add. Add both `trustedtermiteandpest.com` and `www.trustedtermiteandpest.com`. The site canonicalises to **www**, so `www` is the one that must serve the site and the apex should redirect to it. Vercel will show an A record value for the apex and a CNAME target for `www`. Copy both exactly.
- 2 Lower the TTL and wait an hour.** In Landingsite's DNS panel, set the TTL on the apex A records and the `www` CNAME to `60` seconds. Save, then wait a full hour for the old one-hour TTL to age out. This is the step everyone skips and it is the one that buys you a one-minute rollback instead of a one-hour outage.
- 3 Replace the apex A records.** Delete *both* existing values — `166.117.246.71` and `75.2.29.147` — and add a single A record with the value from your Vercel domain card. Leaving one behind means half your visitors land on the old site at random.
- 4 Repoint the www CNAME.** Change the target from `proxy-ssl.getlandingsite.com` to the CNAME value Vercel gave you. Copy it *including the trailing dot* if Vercel shows one — that dot is deliberate and Vercel's docs call out omitting it as a common failure.
- 5 Leave the Google verification TXT alone.** Do not tidy it up. It is what keeps Search Console verified.
- 6 Watch it change.** Run the checks in §6. Within a few minutes the answers should be the new ones. Vercel's domain page should move from *Invalid Configuration* to configured, and it will issue an SSL certificate on its own once the domain resolves to it.
- 7 Load the site in a private window, on mobile data.** Not your normal browser — your machine and your office network cache aggressively. Check the apex and the `www` address, and check that `http://` upgrades to `https://`.
- 8 Put the TTL back to 3600** once you are satisfied, a day or two later. A permanent 60-second TTL is extra lookups for no benefit.

What the controls will be called

Panels differ, but the wording clusters. Look for **DNS**, **DNS Records**, **Advanced DNS**, **Zone Editor**, **Manage DNS** or **Custom Domain**. Records are usually a table with **Type**, **Name** (sometimes Host), **Value** (sometimes Points to, Target, Content) and **TTL**.

One syntax trap. In the *Name* field, the apex is written as `@` or left blank — never the full domain. The `www` record is written as just `www`, not `www.trustedtermiteandpest.com`. Vercel's troubleshooting page lists putting the whole domain in the Name field as a common error, because some panels then silently create `www.trustedtermiteandpest.com.trustedtermiteandpest.com`.

If the panel has no DNS editor at all — some builder platforms hide it — then Route A is not available to you and you are going to Route B, or asking Landingsite support to make the two changes for you in writing.

5 · Route B, step by step

⚠ Copy the whole zone before you switch anything

Changing nameservers does not migrate your records — it abandons them. Vercel's documentation states it plainly: you "will need to add any DNS records to Vercel that you wish to keep from your previous DNS provider." Anything you did not re-create simply stops existing.

- 1 **Screenshot or export every record** in the Landingsite DNS panel. §1 of this document is a snapshot taken on 27 August 2026 and is a reasonable cross-check, but the live panel may hold records that do not show up in a public lookup.
- 2 **Add the domain to Vercel and choose the nameserver method.** Vercel will give you its nameserver hostnames.
- 3 **Re-create the records at Vercel first.** At minimum the Google verification TXT. There are no MX records to carry, which is the one piece of luck here.
- 4 **Get into the Name.com account.** This is the step that may need Landingsite's cooperation — see §8. Change the nameservers from `ns1-ns4.landingsite.ai` to Vercel's.
- 5 **Wait.** Nameserver changes take up to 24–48 hours to propagate fully. During that window some visitors see the old site and some the new one. This is normal and it is why Route B is not a Friday-afternoon job.
- 6 **Re-verify in Google Search Console** once propagation settles, and confirm the site loads on both the apex and www.

6 · How to check, without trusting anybody's dashboard

Run these from a terminal. They query public DNS directly, so they tell you what the world sees rather than what a control panel claims.

```
dig ns trustedtermiteandpest.com +short
dig a trustedtermiteandpest.com +short
dig cname www.trustedtermiteandpest.com +short
dig txt trustedtermiteandpest.com +short
```

No terminal? Use `dns.google` in a browser and set the record type, or `dnschecker.org` to watch propagation across regions. Both are free and neither needs an account.

If SSL does not appear: Vercel issues certificates through Let's Encrypt automatically once the domain points at it. The two usual blockers are a CAA record that does not permit Let's Encrypt and a stale `_acme-challenge` TXT record. As of the date stamped on this document, **this domain has neither**, so a certificate should issue without intervention.

7 · Rollback — the page to print before you start

If the new site does not come up, put these back exactly and the old site returns. With the TTL lowered to 60 seconds first, this takes effect in about a minute.

TYPE	NAME	VALUE TO RESTORE
A	@	166.117.246.71
A	@	75.2.29.147
CNAME	www	proxy-ssl.getlandingsite.com
TXT	@	google-site-verification=L4b3yuf1vGMR_ceV2JK9tA-VAH5X0ZEhq4yAM1JtnL8
NS	@	ns1.landingsite.ai · ns2.landingsite.ai · ns3.landingsite.ai · ns4.landingsite.ai

Rolling back is not a failure. It is the reason the TTL was lowered in step 2, and a cutover you can reverse in a minute is worth more than one you got right first time by luck.

8 · What to ask Landingsite for, in writing

Ask by email rather than by phone, so there is a record of what was agreed. Four things:

- **The notice period on the monthly agreement** — so the old service is not switched off mid-cutover, and so nobody pays two vendors for a month longer than necessary.
- **Confirmation of who controls the Name.com account** holding the domain, and access to it, or the transfer lock lifted and an auth code issued.
- **Confirmation that the domain renewal on 29 October 2026 is covered**, and who is paying it.
- **Confirmation they will not disable DNS** for the domain when the hosting agreement ends. Under Route A they are still answering DNS for you after the site has moved, and that dependency should be acknowledged rather than assumed.

None of this is adversarial. A vendor being replaced still has obligations, and asking clearly in writing is how both sides avoid an argument later.

9 · If something looks wrong

SYMPTOM	MOST LIKELY CAUSE
Vercel says <i>Invalid Configuration</i>	The record has not propagated yet, or an old conflicting record is still present. Vercel's guidance is to remove outdated records to prevent conflicts — check that <i>both</i> old apex A records are gone.
Site loads for you, not for others	Local DNS cache. Try mobile data and a private window; flush your DNS cache.
www works, apex does not	The apex needs an A record, not a CNAME — a CNAME at the zone apex is invalid per the DNS spec and Vercel calls this out specifically.
CNAME rejected or behaves oddly	Trailing dot dropped, or the full domain typed into the Name field instead of just <code>www</code> .
No padlock / SSL warning	Certificate not issued yet. Give it time; then check for a CAA record or a stale <code>_acme-challenge</code> TXT. Neither existed on 27 Aug 2026.
Half the visitors see the old site	Mid-propagation, or one of the two old A records was left in place.

Sources. Live DNS and RDAP registry lookups for `trustedtermiteandpest.com` , read 27 August 2026. Vercel documentation: *Adding & Configuring a Custom Domain*, *Troubleshooting domains*, and *Can I use my domain on Vercel with A records?* — all last updated 11 August 2026.

Landingsite's own control panel is not documented here because we have no access to it and could find no public documentation. Where this guide could not verify something, it says so rather than filling the gap.
